In both the modes, the auxiliary circuit provides ZVS turn-on of the switches. The auxiliary circuit consists of two IGBTs SH ...

In general, the choice of an ESS is based on the required power capability and time horizon (discharge duration). As a result, the type of service required in terms of energy density (very short, short, medium, and long-term storage capacity) and power density (small, medium, and large-scale) determine the energy storage needs [53]. In addition ...

As shown in Figure 1, the energy storage system can be presented with four characteristics: pure inductance, pure capacitance, positive resistance, and negative resistance, by changing the control strategy to meet the system requirements. As shown in Figure 1A, the voltage phase at the AC network side is the same as that of the electromotive force of the ...

2 Analysis of the proposed converter. Fig. 1 shows the proposed bidirectional converter. In the boost mode, the switch S 2 is operated to accumulate energy in the input inductor L and when the switch S 2 is turned off, the stored energy is delivered to the load through the body diode of S 1. When the converter operates in buck mode, the power to the output will ...

For most of the time in a switching period, auxiliary switch S a is in the ""on"" state, and a current circulates in the auxiliary circuit. Once auxiliary switch S a is turned off, energy in resonant inductor L r will resonate DC bus voltage V bus to zero. Then the main switches can be turned on with ZVS condition.
