How does a flywheel system store energy?

A flywheel system stores energy mechanically in the form of kinetic energy by spinning a mass at high speed. Electrical inputs spin the flywheel rotor and keep it spinning until called upon to release the stored energy. The amount of energy available and its duration is controlled by the mass and speed of the flywheel.

The flywheel continues to store energy as long as it continues to spin; in this way, flywheel energy storage systems act as mechanical energy storage. When this energy needs to be retrieved, the rotor transfers its rotational energy back to a generator, effectively converting it into usable electrical energy. The anatomy of a

Energy is discharged by drawing down kinetic energy using the same motor as a generator. But it is not a primary source of power generation. Extra power in the grid is shunted to the flywheel and used to set them in motion. When the power is required later, the momentum of the flywheel is used to generate power fed back to the grid.
