Power systems in the future are expected to be characterized by an increasing penetration of renewable energy sources systems. To achieve the ambitious goals of the "clean energy transition", energy storage is a key factor, needed in power system design and operation as well as power-to-heat, allowing more flexibility linking the power networks and the heating/cooling ...

Energy storage systems (ESSs) controlled with accurate ESS management strategies have emerged as effective solutions against the challenges imposed by RESs in the power system [6]. Early installations are large-scale stationary ESSs installed by utilities, which have had positive effects on improving electricity supply reliability and security [7, 8].

A significant mismatch between the total generation and demand on the grid frequently leads to frequency disturbance. Energy storage can provide multiple benefits to the grid: it can move electricity from periods of low prices to high prices, it can help make the grid more stable (for instance help regulate the frequency of the grid), and help reduce investment into transmission infrastructure. Any electrical power grid must match electricity production to consumption, both of which vary significantly over time. Any combination of energy storage and demand response has these advantages:
