

Are phase change materials suitable for thermal energy storage?

Phase change materials (PCMs) having a large latent heat during solid-liquid phase transition are promising for thermal energy storage applications. However, the relatively low thermal conductivity of the majority of promising PCMs ($< 10 \text{ W/(m} \cdot \text{K)}$) limits the power density and overall storage efficiency.

Why is phase change energy storage a non-stationary process?

During the phase change process, the temperature of PCM remains stable, while the liquid phase rate will change continuously, which implies that phase change energy storage is a non-stationary process. Additionally, the heat storage/release of the phase change energy storage process proceeds in a very short time.
