

Again, made of cobalt, particularly in the case of LCOs (but non-LCO Li-ion battery cathodes can be made of lithium manganese, nickel, and so on). An Electrolyte. Formed of non-aqueous lithium salt. A Separator. Made of polyolefin (due to its high chemical resistance, which is needed for anode/cathode separation). A Positive Current Collector

The chemistry of a lithium-ion battery requires different materials on the positive and negative sides of the battery. The positively charged cathode is essentially aluminum foil coated in a lithium compound, like lithium iron phosphate (sometimes referred to as LiFePO_4).

Although lower in specific energy than lithium-metal, Li-ion is safe, provided cell manufacturers and battery packers follow safety measures in keeping voltage and currents to secure levels. In 1991, Sony commercialized the first Li-ion battery, and today this chemistry has become the most promising and fastest growing on the market.

number 3, lithium is the lightest metal with a density of only 0.53 g/cm^3 . It also has a very low standard reduction potential (Li^+/Li couple -3.05 V vs SHE), thus making it suitable for high-density, high-voltage battery cells. However, lithium is a relatively reactive metal, which has to be protected from water and air, for example.

Among the many battery options on the market today, three stand out: lithium iron phosphate (LiFePO_4), lithium ion (Li-Ion) and lithium polymer (Li-Po). Each type of battery has unique characteristics that make it suitable for specific applications, with different trade-offs between performance metrics such as energy density, cycle life, safety ...
